Doesn't matter how much you use, but whole block must be consistent

Python Style Guide (PEP 8) recommends 4 spaces

And no tab characters

Side note on IDEs (Integrated Development Environments)

Side note on IDEs (Integrated Development Environments)

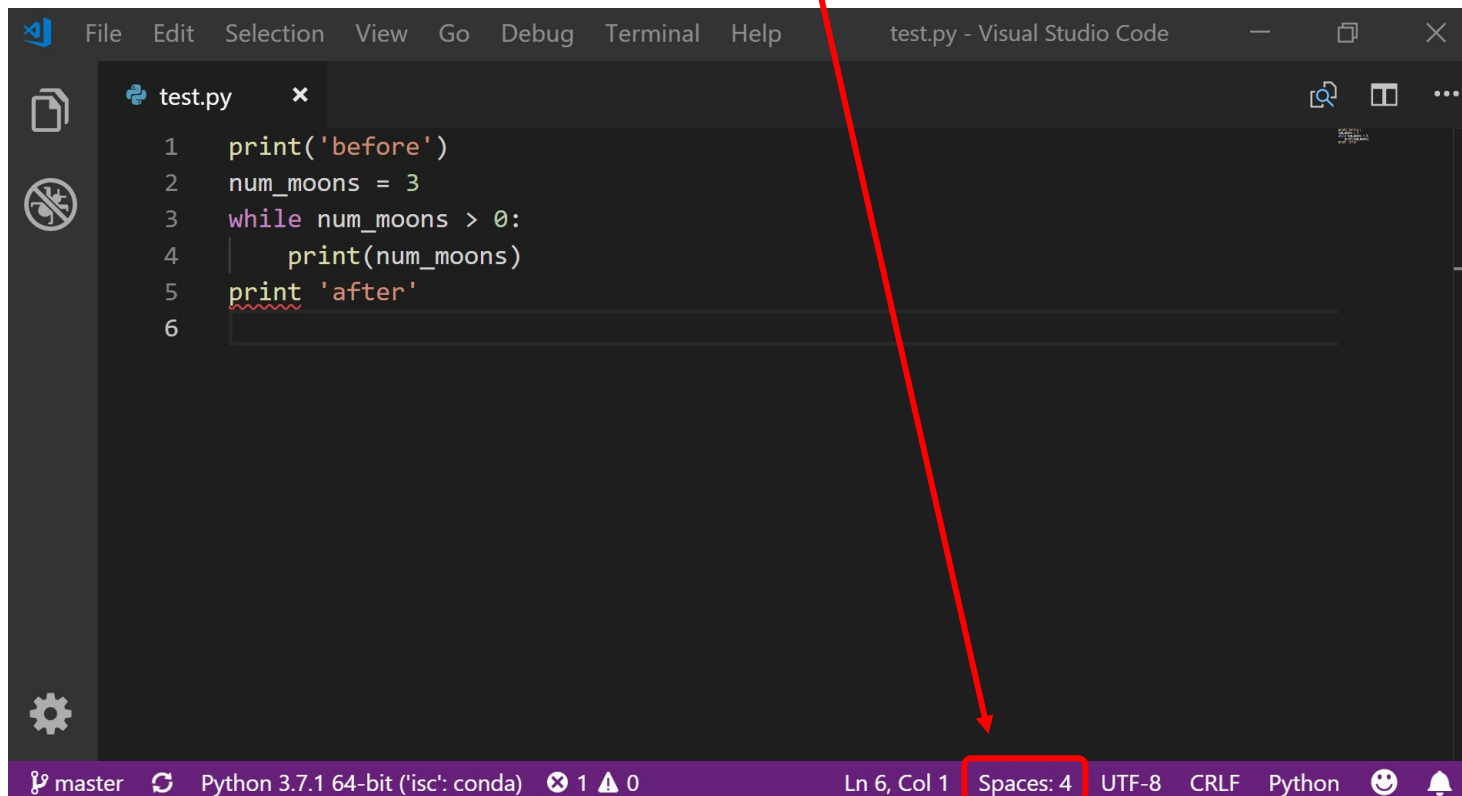

An IDE is a nicer place to write, edit and run code from all in one. Most often also include syntax highlighting, error highlighting and debugging built in (debugging will be taught later in the course).

```
test.py
1  print('before')
2  num_moons = 3
3  while num_moons > 0:
4      print(num_moons)
5  print 'after'
6
```

Side note on IDEs (Integrated Development Environments)

Most IDEs will also let you choose your indentation too, so you don't have to manually type 4 spaces...

```
test.py
1  print('before')
2  num_moons = 3
3  while num_moons > 0:
4      print(num_moons)
5  print 'after'
6
```

Python

Common operators: `and`, `not` `and` `or`

Testing expressions

You may want to create a more complex expression when testing using `if` or `while`.

Testing expressions

You may want to create a more complex expression when testing using `if` or `while`.

```
age = 23
```

```
name = "Jemma"
```

```
height = 1.63
```

← Some variables

Testing expressions

You may want to create a more complex expression when testing using `if` or `while`.

```
age = 23  
name = "Jemma"  
height = 1.63
```

← Some variables

What if we want someone with all of these qualities?

What if we want someone who is some of these qualities?

Introducing the `and`, `not` and `or` operators

You may want to create a more complex expression when testing using `if` or `while`.

```
age = 23
name = "Jemma"
height = 1.63
if age == 23:
    print("Correct age")
if name == "Jemma":
    print("Correct name")
if height == 1.63:
    print("Correct height")
```

Introducing the `and`, `not` and `or` operators

You may want to create a more complex expression when testing using `if` or `while`.

```
age = 23
```

```
name = "Jemma"
```

```
height = 1.63
```

```
if age == 23:
```

```
    print("Correct age")
```

```
if name == "Jemma":
```

```
    print("Correct name")
```

```
if height == 1.63:
```

```
    print("Correct height")
```

Could perform 3 tests to make sure the 3 variables are correct

This seems inefficient

Using and

Block executes only if both expressions return `True`

```
age = 23
```

```
name = "Jemma"
```

```
height = 1.63
```

```
if name == "Jemma" and age == 23:
```

```
    print("It is Jemma!")
```

```
It is Jemma!
```

Using and

and can be chained more than once too:

```
age = 23
```

```
name = "Jemma"
```

```
height = 1.63
```

```
if name == "Jemma" and age >= 20 and height < 2:
```

```
    print("It is like Jemma!")
```

```
It is like Jemma!
```

Using not

`not` will reverse the Boolean result of an expression, we can use it to make blocks that execute only if the expression returns `False` or `None`

```
age = 22
```

```
name = "Rachel"
```

```
height = 1.65
```

```
if not name == "Jemma":  
    print("It isn't Jemma!")
```

It isn't Jemma!

Using not

Can be used to see if variable not in a collection:

```
x = 25
```

```
if x not in [1, 2, 3]:
```

```
    print("Didn't find x in list")
```

```
Didn't find x in list
```

Can even write `is not` to compare:

```
if x is not 100:
```

```
    print("x is not 100")
```

```
x is not 100
```

Using `or`

`or` will return `True` if either or both expressions are `True`:

```
greeting = "Hello"
```

```
if greeting == "Hi" or greeting == "Hello":
```

```
    print("Good day")
```

Good day

Can be chained more than once:

```
x = 25
```

```
if x < 0 or x > 100 or x == 25:
```

```
    print("x is correct")
```

x is correct

Chaining all of these operators

All of these operators can be chained together to create more complex expressions:

```
start = False
```

```
end = 55
```

```
status = "STARTED"
```

```
if status == "STARTED" and (start is not False or end > 0):  
    print("Running")
```

Running

You might need brackets (as above) to specify the precedence of evaluation of expressions.
